

# Principles of GUI Design and Programming

User-Centered Design

# Contents

---

- ▶ User centered design
- ▶ Design process
- ▶ Design in the life cycle

# Approaches to Interaction Design

---

- ▶ **User-centered design**

- ▶ The user guides the designer to develop a design which meets the users needs

- ▶ **Activity centered design**

- ▶ Focuses on the behaviour required to achieve a goal rather than the goal itself

- ▶ **Systems design**

- ▶ Focuses on the whole system of hardware and software to meet the users needs

- ▶ **Genius design**

- ▶ An expert in the field performs the design based on knowledge and experience

# The Design Process

---

- ▶ All of the designs perform the same steps
  - ▶ Determine the requirements
  - ▶ Produce a design to satisfy the requirements
  - ▶ Evaluate the design

# The Importance of Involving Users

---

- ▶ Many designs were done with minimal user involvement
  - ▶ Designers did the design by themselves
  - ▶ Designers communicated with managers who described what was done
- ▶ It was found that users often did things differently than either the designers or managers thought they did
- ▶ This can only be discovered by talking to the users

# The Importance of Involving Users

---

- ▶ **Expectation management**
  - ▶ If the users are not involved in the design process, they can have unrealistic expectations
  - ▶ This can be tempered by involving them in the process so they know what is possible and what to expect
  - ▶ It is better to exceed expectations than to disappoint

# How Much Should Users be Involved?

---

- ▶ Involving users makes them feel part of the process and take ownership
- ▶ Part-time involvement allows users to go back and forth between other users and developers, conveying ideas and staying in touch with both
- ▶ Full-time users involved in design risk becoming designers and losing touch with the other users

# How Much Should Users be Involved?

---

- ▶ **Studies show**
  - ▶ Some user involvement is beneficial
  - ▶ If too many users get involved, it can actually have a negative impact on the project

# Three Principles of Design

---

## 1. Early focus on users and tasks

- ▶ Understand the users by observing them and identifying their characteristics and what they do

## 2. Empirical Measurement

- ▶ Early in the process, how long it takes users to perform tasks and look up information is measured. This can be used to measure performance gains in the final system.

## 3. Iterative Design

- ▶ When problems are found in the design, it is revised and retested.

# Early focus on users and tasks

---

- ▶ The design is driven by the goals and tasks performed by the users
  - ▶ The goal is to see how the technologies can support the users, not what technologies can we use in the project.
- ▶ User's behaviour and context are studied and the system is designed to support them
- ▶ Users' characteristics are captured and designed for.
  - ▶ The design will take into account the limitations of the users

# Early focus on users and tasks

---

- ▶ Users are consulted throughout development
  - ▶ Users are involved and the input is respected by the designers
- ▶ All design decisions are taken within the context of the users
  - ▶ While the users might not be continuously involved, the designers always keep them and their needs in mind when making decisions

# Empirical Measurement

---

- ▶ Specific usability and user experience goals should be identified at the beginning of the project
- ▶ This will allow
  - ▶ Designers to choose between alternatives
  - ▶ Check on the progress of the project
  - ▶ The project to be evaluated during development

# Iterative Design

---

- ▶ Iteration allows designs to be refined based on feedback
- ▶ Even the best designers rarely get things right the first time
- ▶ Iteration allows them to identify problems and return to the design to correct them

# Four Basic Activities of Interaction Design

---

## 1. Establishing Requirements

- ▶ Understanding the behaviour and needs of the users is fundamental to a user-centered approach

## 2. Designing Alternatives

- ▶ Different designs are considered

## 3. Prototyping

- ▶ Paper based models (or computer based) are built and evaluated

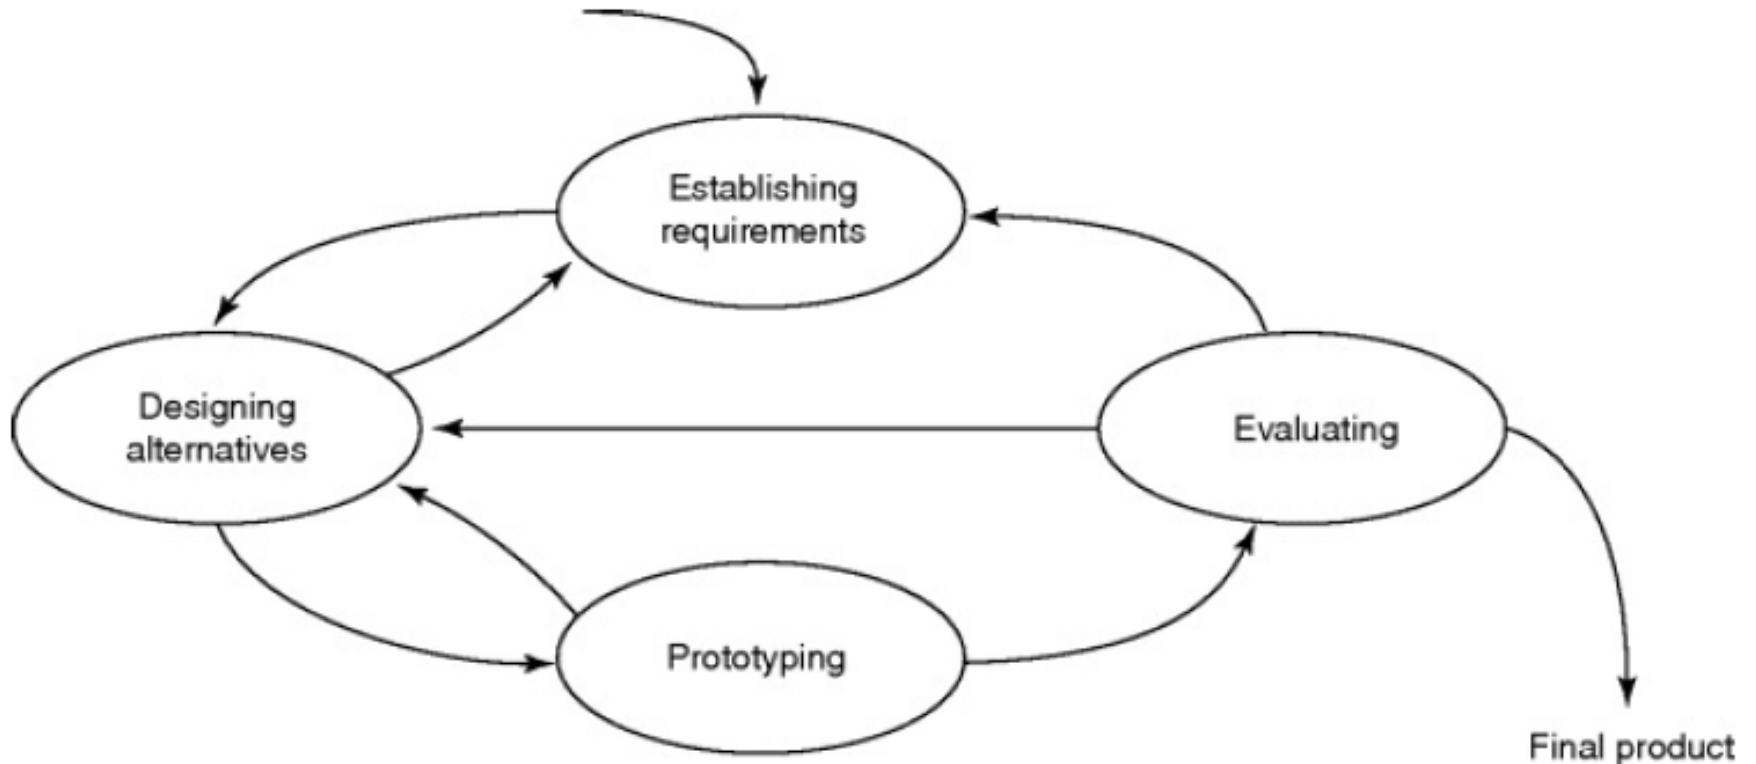

## 4. Evaluating

- ▶ This determines the usability and acceptability of the design alternatives

# A simple interaction design lifecycle model

---

# Who Are the Users?

---

- ▶ Direct users of the system
- ▶ People who manage the direct users
- ▶ One idea was to have primary, secondary and tertiary users
- ▶ Better to identify all stakeholders and select those who are best able to identify the requirements

# What Do We Mean by 'Needs'?

---

- ▶ Users often cannot tell you their needs because they do not know what is possible with the technology
- ▶ Focusing on people's usability and user experience goals is more promising than focusing on people's needs and expecting them to be able to tell us the requirements for a product.

# How Do You Generate Alternative Designs?

---

- ▶ Cross-fertilization of ideas with other designers
- ▶ Have stakeholders work with designers to identify analogies between their field and the new area
- ▶ Look at other designs you can borrow ideas from

# How Do You Choose Among Alternative Designs?

---

- ▶ These decisions will be informed by
  - ▶ The information gathered about users and their tasks,
  - ▶ and by the technical feasibility of an idea.
- ▶ In design there are
  - ▶ Externally observable features and behaviour
  - ▶ Internal structure and behaviour
- ▶ End users are only concerned about external visibility, not the internals necessary to make it happen
- ▶ Make internal decisions based on external needs

# How Do You Choose Among Alternative Designs?

---

- ▶ Let the users interact with prototypes of each alternative and discuss the pros and cons of each
- ▶ Select the alternative which is going to give the best quality interface

# How Do You Integrate Design with Other Lifecycle Models?

---

- ▶ An ongoing question is
  - ▶ How do we integrate design with software development life cycle models?
- ▶ Current software lifecycle models are focusing on agile methods which
  - ▶ Involve users in the process
  - ▶ Do many iterations and get frequent user feedback
  - ▶ Test continually throughout the development process
- ▶ These ideas are in line with the requirements of interface design
